Impingement syndrome and associated rotator cuff tears are commonly encountered shoulder problems. This condition is caused when the rotator cuff tendons rub the underside of the acromion bone. Chronic rubbing can lead to a weakening and even tearing of the rotator cuff. Symptoms include pain, weakness and loss of motion. Whether this procedure is done using a scope or through a small incision is dependent on the severity of the tear and the doctor's preference. The method shown in these animations is with a scope.
Subacromial Decompression Introduction
Impingement syndrome and associated rotator cuff tears are commonly encountered shoulder problems. This condition is caused when the rotator cuff tendons rub the underside of the acromion bone. Chronic rubbing can lead to a weakening and even tearing of the rotator cuff. Symptoms include pain, weakness and loss of motion. Whether this procedure is done using a scope or through a small incision is dependent on the severity of the tear and the doctor’s preference. The method shown in these animations is with a scope.

Doctor’s Personal Note: A Message From Your Doctor
Thank you for visiting our website and viewing our 3D Animation Library. These animations should assist you in better understanding your condition or procedure. We look forward to answering any additional questions you may have at our next appointment.

Rotator Cuff Pain
The underside of the acromion bone rubs the rotator cuff tendons causing pain and weakness. More space will be created for the rotator cuff by removing part of the acromion.
**Incisions**
Small incisions (portals) are made around the joint. The scope and surgical instruments will go into these incisions.

**Visualization**
The scope is inserted into the back of the shoulder joint. Saline solution flows through a tube (cannula) and into the bursa sac to expand the joint and to improve visualization. The image is sent to a video monitor where the surgeon can see inside the joint.

**Bursa Sac and Coracoacromial Ligament Removal**
A specialized surgical instrument is used to remove the inflamed and irritated bursa sac. Next, a surgical instrument is inserted into the joint and, based on surgeon discretion (or decision) the coracoacromial ligament is removed.
Removing Bone
A surgical bur is used to remove bone from the underside of the acromion. More space is created for the rotator cuff tendons.

End of Procedure
After more space has been created between the acromion and the rotator cuff, the surgical instruments are removed and the procedure is completed.
